

Which ticket was the most realistic and why?

I believe that one of the most realistic tickets that was created was the VPN connectivity issue due to the fact that many companies rely on remote access for employees. Troubleshooting the VPN problems required me to go through a number of steps like checking for connectivity, login credentials, MFA authentication, and VPN client settings. This ticket felt realistic because it involved both networking but also user support skills while also requiring communication with the user throughout the troubleshooting process. It helped me better understand how IT support technicians must think through multiple causes and effects before coming down to the root cause and enabler.

How did you decide ticket priority

I decided ticket priority based on how much the issue affected the users ability to work but also how much the company would be impacted by this problem. For example, account lockouts and VPN failures were marked as high priority due to the fact that users were not able to access important systems and be able to complete their job. Printer issues on the other hand and slower computer performance were marked as medium priority because work could still continue there would just be a bit of constraints. Hardware issues like a monitor problem were considered lower priority if temporary alternatives were available. This project was able to teach me the importance but also made me able to navigate my way through what has higher priority.

Why is documentation important in helpdesk work?

Documentation is important in the help desk work space because it keeps track of what issue occurred, what troubleshooting steps were taken, and how the issue was resolved; or not resolved. Proper documentation allows for other people who might view the ticket to be able to diagnose and understand what happened, especially in the sense of escalation. During this lab, I learned that documentation should be clear, organized, and professional so that it leads to more efficient troubleshooting.

What troubleshooting step did you learn that you could use in a real job?

One troubleshooting step that I learned that would be useful in a real job would be starting my way from the bottom of complexity and working my way up. When it comes to fixing problems, there can be a multitude of ways in order to solve them, however it is about how efficient and effective you get to that solution. And it made me learn that yes, problems can be big and small yet you have to think level headed and work your way up to the more complex issues to save time.

How would you explain this project in an interview?

In an interview, I would explain this project as a simulated helpdesk environment where I practiced real IT support workflows using Freshdesk. I created and managed multiple support tickets involving account access, networking, hardware, software, and security-related issues. I documented troubleshooting steps, assigned priorities, managed ticket statuses, and followed the full ticket lifecycle.
